

# Triaging a citation-accuracy ticket

Quick reference for a support specialist · Sample work by Alex Donnelly · [ajdonnelly.github.io/harvey-support-enablement](https://ajdonnelly.github.io/harvey-support-enablement)

## About this sample

Independent work sample built only from Harvey's public product information. Not affiliated with, authorized by, or endorsed by Harvey. No confidential or internal material; steps, thresholds, and tags are illustrative and would be replaced with real ones on the job.

## WHY THIS TICKET MATTERS

Citations are how a user verifies a Harvey answer before relying on it — checking a claim against its source is core to trusting the product. A citation that looks wrong isn't cosmetic to the user; it's a question about whether they can trust the tool at all. How you handle it shapes confidence well beyond the single ticket.

## CLASSIFY THE REPORT IN ONE READ

"Citation accuracy" is almost always one of four things. Naming which decides everything that follows:

- **Wrong link** — the citation opens the wrong place.
- **Mismatch** — the cited source doesn't support the sentence.
- **Missing source** — a claim with no citation at all.
- **Scope** — the user expected a source Harvey wasn't given access to.

## THE 5-STEP TRIAGE PATH

*Work top to bottom. Most tickets resolve by step 3.*

1. **Reproduce the scope** — confirm what sources the query ran over (uploads, a Vault, a DMS connection, premium databases, web). Harvey can only cite what it was given.
2. **Open the citation** — click through and read the cited passage against the sentence it supports; decide which of the four categories you're in.
3. **Check for a known pattern** — long multi-source documents and look-alike versions are the usual culprits; confirm the user is on the current version of the source set.
4. **Coach the verification habit** — show the user how to expand a citation and confirm a claim at the source before relying on it. Resolves the moment and prevents the next ticket.
5. **Decide: resolve or escalate** — scope, version, or how-to: resolve and document. Source genuinely doesn't support the claim: escalate.

## QUICK REFERENCE: SYMPTOM → CAUSE → ACTION

| What the user reports                          | Most likely cause                               | Specialist action                                                              |
|------------------------------------------------|-------------------------------------------------|--------------------------------------------------------------------------------|
| "The citation links to the wrong document."    | Near-duplicate or superseded version            | Confirm active version; re-run over correct file/Vault; document               |
| "The source doesn't actually say this."        | Substantive claim/source mismatch               | Capture query + answer + cited passage; ESCALATE                               |
| "This claim has no citation."                  | Unsupported assertion; treat as unverified      | Advise user not to rely on it; reproduce; escalate if repeatable               |
| "It ignored a document I expected."            | Source-scope mismatch / not synced              | Check scope & DMS sync; re-run with source included; resolve                   |
| "Citations changed when I re-asked."           | Prompt phrasing variance                        | Share a clearer prompt pattern; point to prompt library; resolve               |
| "Where does this data go? Do you train on it?" | A data-security question, not an accuracy issue | Give the headline answer (below); route specifics to the security/trust portal |

## ESCALATE WHEN...

- The source truly doesn't support the claim (reproducible mismatch) — attach query, answer, cited passage.
- It repeats across queries or users — a signal, not a one-off.
- It touches data scope or security / permissions — escalate immediately.
- A key account's trust is shaken — loop in the lead so the relationship is handled, not just the ticket.

**Always log the category**

Tag every citation ticket with one of the four categories before closing it. That tag turns scattered tickets into a trend the enablement and QA teams can act on — and is how a recurring mismatch becomes the next training module instead of a hundred separate conversations.

## WHEN IT'S A DATA QUESTION, NOT AN ACCURACY ONE

---

Citation tickets often shade into “...and where is our data going?” — a different class of question. Don’t run the triage above; answer the headline confidently and route the specifics.

- **Do you train on our data?** — No; Harvey contractually guarantees it doesn’t use your inputs, outputs, or uploads to train the models.
- **Where is our data stored?** — In-region (EU/Switzerland, US, or Australia); customers control upload, retention, and deletion.
- **Who can see it?** — SAML SSO, audit logs, IP allow-listing, and in-product permissions govern access.
- **Independently checked?** — SOC 2 Type II, ISO 27001 / 27701 / 42001, GDPR, CCPA, plus third-party audits.

### Know the headlines; route the details

Answer the four above with confidence. For specific contractual, compliance, or configuration questions, point the user to the security/trust portal and loop in the right internal team. A subtly wrong security answer does more damage than “let me get you the precise answer” — when unsure, route, don’t guess.
